In Phase 3 of the Final Assignment, I have completed the first three bullet points in the section, "What Goes in the Jupyter Notebook". I have not made a model yet or done any metrics on it. I have stated the problem statement. The problem statement is, "By looking at a golfer's past performance statistics, will the athlete be within the top 10 of the PGA Tour tournament?". I have determined this problem is a supervised prediction task because the data is based off of past PGA golf athlete performance statistics and the goal is to future predict if each golfer would make it in the top 10 of the PGA Tour tournament. In the dataset, there were three columns with missing values, some rows were blank, and some data was duplicated. The columns with missing values, the rows that are blank, and the duplicated data are removed. I made some visualizations to see the key relationships in the data. I made density plots about the number of strokes gained in total for the most recent tournament and the number of strokes gained in total for the prior 5 tournaments. I found that past scores of players who made in the top 10 of the tournaments and those who did not are very similar. I then made a correlation matrix comparing features related to a player's prior tournament form against the Top 10 target for a current tournament. I found that no single stat would predict a top 10 finish by itself. I then made boxplots about the prior 5 tournament strokes gained and the prior 5 tournament players that made the cut. I found that players in the top 10 have a higher chance of making the cut in the tournament.
